

Influenza: Diagnosis and Treatment

David Y. Gaitonde, MD; Cpt. Faith C. Moore, USA, MC; and Maj. Mackenzie K. Morgan, USA, MC

Dwight D. Eisenhower Army Medical Center, Fort Gordon, Georgia

Influenza is an acute viral respiratory infection that causes significant morbidity and mortality worldwide. Three types of influenza cause disease in humans. Influenza A is the type most responsible for causing pandemics because of its high susceptibility to antigenic variation. Influenza is highly contagious, and the hallmark of infection is abrupt onset of fever, cough, chills or sweats, myalgias, and malaise. For most patients in the outpatient setting, the diagnosis is made clinically, and laboratory confirmation is not necessary. Laboratory testing may be useful in hospitalized patients with suspected influenza and in patients for whom a confirmed diagnosis will change treatment decisions. Rapid molecular assays are the preferred diagnostic tests because they can be done at the point of care, are highly accurate, and have fast results. Treatment with one of four approved anti-influenza drugs may be considered if the patient presents within 48 hours of symptom onset. The benefit of treatment is greatest when antiviral therapy is started within 24 hours of symptom onset. These drugs decrease the duration of illness by about 24 hours in otherwise healthy patients and may decrease the risk of serious complications. No anti-influenza drug has been proven superior. Annual influenza vaccination is recommended for all people six months and older who do not have contraindications. (*Am Fam Physician*. 2019;100(12):751-758. Published online November 11, 2019

Influenza is an acute respiratory infection caused by a negative-strand RNA virus of the Orthomyxoviridae family. There are three distinct types of influenza viruses that infect humans: influenza A, B, and C. Influenza A infects multiple species, including humans, swine, equines, and birds. It is more susceptible to antigenic variation and, hence, is the cause of major pandemics.^{1,2} The surface of the virion envelope is covered with proteins hemagglutinin (HA), neuraminidase (NA), and matrix 2.¹ Antigenic variation is associated with changes in the HA or NA surface proteins and is generally classified as antigenic drift or shift.¹ Antigenic drift involves small, gradual amino acid substitutions of the HA or NA proteins that can result in smaller outbreaks. Antigenic shift occurs when there are significant changes in the HA or NA proteins that create

novel influenza subtypes with the potential to cause widespread pandemics.^{1,3} Each influenza A subtype is characterized by numbering both the HA and NA proteins (e.g., H3N2, H5N1).

Epidemiology

From 2010 to 2018, estimated seasonal influenza activity in the United States ranged from 9.3 million to 49 million cases and 12,000 to 79,000 deaths per year.⁴ The 2017-2018 influenza season was the third most severe since 2003-2004 and was characterized by high severity of disease in all age groups.⁵ Most cases were secondary to the A/H3N2 subtype, and low vaccine effectiveness was a significant contributing

TABLE 1

People at Increased Risk of Complications from Influenza

People with coexisting medical conditions

Any condition that may compromise the handling of respiratory secretions (e.g., neuromuscular diseases, cerebral palsy, stroke, seizure disorder, dementia)

Asthma or other chronic pulmonary disease

Chronic kidney disease

Chronic liver disease

Heart disease (acquired or congenital)

Immunosuppression (e.g., HIV infection, cancer, transplant recipients, use of immunosuppressive medications)

Long-term aspirin therapy in patients younger than 19 years

Metabolic disorders (acquired [e.g., diabetes mellitus] or inherited [e.g., mitochondrial disorders])

Morbid obesity

Sickle cell anemia and other hemoglobinopathies

Special groups

Adults 65 years and older

American Indians and Alaska Natives

Children younger than 5 years (particularly those younger than 2 years)

Institutionalized adults (e.g., residents of nursing homes or chronic care facilities)

Pregnant and postpartum women (up to 2 weeks postpartum, including pregnancy loss)

factor.⁵ Based on public health laboratory specimens, the predominant influenza A subtype for the 2018-2019 season was (H1N1)pdm09 (56.6% of positive specimens), followed by the A/H3N2 subtype (43.6%) and influenza B (4%).⁶

Seasonal influenza occurs primarily in the colder months in temperate regions. The primary mode of transmission is via inhalation of infectious respiratory particles (large droplet transmission) when an infected person coughs or sneezes. There is also evidence of airborne (small particles transmitted by talking or exhalation) and fomite transmission.^{6,7} The typical incubation period is 24 to 48 hours. Patients are infectious one to two days before symptom onset and for five to seven days afterward. Children and immunosuppressed people may exhibit prolonged viral shedding.^{8,9}

In 2009, a novel H1N1 subtype (pH1N1) emerged from a quadruple reassortment of two swine viruses, one avian virus, and one human virus.¹⁰ First identified in Mexico in 2009, it caused millions of cases worldwide and an estimated 18,500 laboratory-confirmed deaths.¹¹

Since 2011, outbreaks of a swine-origin H3N2 virus have been reported in the United States. Cases predominantly involved young children exposed to swine, often at agricultural fairs.^{12,13} Additionally, the H5N1 avian influenza virus has become a global concern. First identified solely in wild geese populations in China in 1997, the virus quickly spread to domestic poultry and ultimately to human populations. There are now avian influenza cases reported worldwide, although poultry-to-human and human-to-human transmission remains relatively low. Despite low transmissibility, the reported fatality rate is high (approximately 60%).¹⁴

Prevention

The Centers for Disease Control and Prevention's (CDC's) Advisory Committee on Immunization Practices (ACIP) and the American Academy of Family Physicians (AAFP) recommend annual influenza vaccination for all people six months and older who do not have contraindications.^{15,16} Vaccination efforts should target people at increased risk of complicated or severe influenza (*Table 1*¹⁷⁻¹⁹) and those who care for or live with high-risk individuals, including health care professionals.¹⁵ Two previous *FPM* articles provided communication strategies and tools for increasing influenza vaccination rates in practice.^{20,21}

Multiple formulations of the influenza vaccine are available, including inactivated influenza vaccines (IIV); a recombinant inactivated vaccine (RIV); and a live, attenuated influenza vaccine (LAIV). For physicians and patients concerned about egg allergy, quadrivalent RIV and cell culture-based quadrivalent IIV are completely egg-free.¹⁵

An age-appropriate IIV or RIV is suitable for most patients; LAIV is contraindicated in pregnant women,

immunosuppressed people, children younger than two years, children two to four years of age who have had asthma or wheezing in the past 12 months, and adults 50 years and older.¹⁵ For children six months to eight years of age, two doses of IIV administered at least four weeks apart are recommended if the child has not received at least two doses of the influenza vaccine previously. RIV is not licensed for children younger than 18 years.¹⁵

In August 2019, ACIP recommended that LAIV may be used in age-appropriate patients without contraindications for the 2019-2020 influenza season because it was deemed as effective as the IIV for prevention of the H3N2 and influenza B viruses.^{15,22} Notably, influenza-specific antiviral medications may reduce the effectiveness of LAIV if given within two days before to 14 days after vaccine administration.¹⁵ The AAFP has made a preferential recommendation for vaccination with IIV over LAIV.¹⁶

A high-dose, inactivated trivalent vaccine (Fluzone High-Dose) is licensed for adults 65 years and older, and multiple studies show superior effectiveness compared with the standard-dose trivalent IIV (number needed to treat to prevent one additional case of laboratory-confirmed influenza = 220

SORT: KEY RECOMMENDATIONS FOR PRACTICE

Clinical recommendation	Evidence rating	Comments
Annual influenza vaccination is recommended for all people 6 months and older. ^{15,16}	A	Reports of expert committees
The decision to begin antiviral treatment should be based on the clinical diagnosis of influenza, not on test results. Laboratory diagnosis should be obtained when results will change clinical management and for patients with severe illness. ^{19,28}	C	Reports of expert committees
Patients with severe illness or who are at high risk of complications from influenza should receive antiviral treatment regardless of symptom duration, although early treatment is most beneficial. ^{18,28}	B	Observational studies and a meta-analysis of observational studies
Oseltamivir (Tamiflu), peramivir (Rapivab), baloxavir (Xofluza), or zanamivir (Relenza) may be considered to reduce symptom duration in patients with influenza or influenza-like illness, but only if administered within 48 hours—and ideally 24 hours—of symptom onset. ^{18,28}	A	Systematic review of randomized trials
Oral oseltamivir is the preferred treatment for influenza during pregnancy. ^{18,28}	B	Pharmacokinetic studies and cohort studies

A = consistent, good-quality patient-oriented evidence; **B** = inconsistent or limited-quality patient-oriented evidence; **C** = consensus, disease-oriented evidence, usual practice, expert opinion, or case series. For information about the SORT evidence rating system, go to <https://www.aafp.org/afpsort>.

compared with standard-dose vaccine).^{23,24} An adjuvanted inactivated trivalent vaccine (Fluad) is also licensed for use in adults 65 years and older.¹⁵

Clinical Manifestations and Complications

Influenza most often causes an uncomplicated respiratory infection with cough, fever, myalgias, chills or sweats, and malaise that persists for two to eight days. Onset is typically rapid. Atypical gastrointestinal symptoms such as vomiting and diarrhea can occur in children. A minority of patients, especially older adults, young children, and those with medical comorbidities, will experience severe disease due to viral or secondary bacterial pneumonia with respiratory and multiorgan failure.^{8,25} Extrapulmonary complications are rare (Table 2).^{8,19,25-27}

History and Physical Examination

In outpatient and emergency department settings, testing for influenza virus is not necessary to start antiviral treatment in a patient with suspected influenza infection, especially during seasons when influenza A and B viruses are circulating in the local community.^{19,28} Rather, the diagnosis is made clinically based on presenting signs and symptoms, or if the patient has a suspected influenza-associated complication, such as exacerbation of a chronic disease, concomitant pneumonia, or rhabdomyolysis.^{19,28}

A symptom-only clinical prediction rule may aid clinicians in diagnosing influenza.²⁹ It assigns 2 points for fever and cough, 2 points for myalgias, 1 point for chills or sweats, and 1 point for symptom onset within the past 48 hours. Patients with 2 or fewer points are at low risk of influenza, whereas those with 4 or more points are at high risk and may be considered for empiric treatment.²⁹

Diagnostic Testing

According to the CDC, influenza testing can be considered when the results will modify management or when a patient with signs or symptoms of influenza is hospitalized.¹⁹

TABLE 2

Complications of Influenza

Cardiovascular ²⁶	Ocular ²⁶
Cerebrovascular accidents	Conjunctivitis (most common)
Ischemic heart disease	Optic neuritis

Information from reference 31.

Similarly, the Infectious Diseases Society of America (IDSA) suggests testing if the results will curtail the use of unnecessary antibiotics or laboratory testing, or result in prophylactic treatment of high-risk household contacts.²⁸ A prospective study performed at a university health clinic found that rapid polymerase chain reaction testing decreased antibiotic prescriptions as well as the likelihood of the patient returning for a second visit within two weeks.³⁰

There are several types of point-of-care diagnostic tests for influenza. In otherwise healthy outpatients, more expensive rapid molecular assays may be preferred because of their higher sensitivity compared with other rapid testing methods.²⁸ Because of the prolonged time to obtain results from viral culture or reference laboratory polymerase chain reaction testing, these tests are not practical for clinical decision-making in influenza management. Table 3 summarizes the accuracy and estimated positive and negative predictive values of point-of-care influenza tests in low- and high-prevalence populations.³¹

Treatment

Treatment with an anti-influenza drug is an option, with the decision to prescribe based on balancing potential benefits, harms, cost, and patient preferences. In otherwise healthy

adults and children, the clinical benefit is greatest when treatment is initiated within 24 hours of symptom onset.²⁸ Although anti-influenza drugs have been approved by the U.S. Food and Drug Administration for use within 48 hours of symptom onset, most clinical trials enrolled patients who had been symptomatic for no more than 36 hours. The primary benefit of treatment is a decrease in symptom duration by approximately 24 hours when treatment is initiated within 36 hours, and a reduction in disease severity.^{32,33} Among adults and children with influenza in the outpatient setting who are treated with an NA inhibitor, systematic reviews of published and unpublished randomized trials found no decrease in hospitalizations or death.^{29,33} However, in hospitalized adults and children, three observational studies found an association between the use of NA inhibitors and mortality benefit.³⁴⁻³⁶

The CDC and the IDSA recommend antiviral therapy for patients with severe or progressive illness, who are at high risk of influenza-associated complications, or who are hospitalized.^{18,28} Although early treatment is most beneficial, treatment should be initiated in these patients regardless of symptom duration.²⁸ The IDSA also recommends that treatment be considered for household contacts of people at high risk of influenza-associated complications.²⁸

TABLE 4

Treatment of Influenza

Drug/formulation	Cost*	Dosages	FDA-approved indications	Contraindications and precautions
Oseltamivir (Tamiflu), available as oral capsules or suspension	\$50 to \$100 (\$160 to \$310) depending on dosage	Adults and children 13 years and older: 75 mg 2 times per day for 5 days Children: 2 weeks to < 12 months of age (any weight): 3 mg per kg 2 times per day for 5 days < 33 lb (15 kg): 30 mg 2 times per day for 5 days 33 to 50 lb (15 to 23 kg): 45 mg 2 times per day for 5 days > 50 to 88 lb (23 to 40 kg): 60 mg orally 2 times per day for 5 days > 88 lb (40 kg): adult dosage	Prevention of influenza A and B in patients 12 months and older Treatment of uncomplicated acute influenza A and B in patients 2 weeks and older who have been symptomatic for no more than 48 hours	Contraindicated in people with serious hypersensitivity to oseltamivir or any component of the product Potential adverse effects include nausea, vomiting, and allergic reactions (e.g., rash, facial swelling) May use during pregnancy; preferred drug for influenza treatment; consider increased dose in pregnant women who are hospitalized with influenza complications; risk of embryo-fetal toxicity not expected based on human data
Zanamivir (Relenza), available as powder for inhalation Intravenous formulation available only as an emergency investigational new drug	NA (\$65)	Adults and children 7 years and older: 10 mg 2 times per day for 5 days (2 doses should be taken on the first day of treatment, provided there is at least 2 hours between doses; on subsequent days, doses should be about 12 hours apart at approximately the same time each day)	Prevention of influenza A and B in patients 5 years and older Treatment of uncomplicated acute influenza A and B in patients 7 years and older who have been symptomatic for no more than 48 hours	Contraindicated in people with milk allergy, underlying reactive airway disease (e.g., asthma, chronic obstructive pulmonary disease), or history of allergic reaction to zanamivir or any component of the product Potential adverse effects include headaches, diarrhea, nausea, vomiting, allergic reaction, nasal symptoms, bronchitis, cough, sinusitis, dizziness, fever, chills, arthralgia, and articular rheumatism; serious and sometimes fatal cases of bronchospasm have occurred May use during pregnancy; risk of embryo-fetal toxicity not expected based on human data

continues

Clinicians caring for high-risk patients can also be considered for treatment.²⁸

Four antiviral drugs have been approved for the treatment of influenza (Table 4): the NA inhibitors oseltamivir (Tamiflu), zanamivir (Relenza), and peramivir (Rapivab), and the cap-dependent endonuclease inhibitor baloxavir (Xofluza).^{18,37} Any of these agents can be used in age-appropriate, otherwise healthy outpatients with uncomplicated influenza and no contraindications.¹⁸ Baloxavir is indicated for the treatment of uncomplicated influenza in patients 12 years and older.³⁸ In a study comparing baloxavir with oseltamivir and placebo in 1,436 otherwise healthy people 12 to 65 years of age who had influenza, oseltamivir and baloxavir reduced symptom duration by approximately one day compared with placebo.³⁸ Symptom duration was

reduced by approximately 32 hours when oseltamivir or baloxavir was given within 24 hours of symptom onset, but only 13 hours if given 24 to 48 hours after onset.³⁸ Given their cost, modest benefits, and adverse effects (primarily nausea and vomiting with oseltamivir), these drugs are not routinely recommended for otherwise healthy patients with influenza.³⁹

Oseltamivir is the preferred treatment for patients with severe influenza. Intravenous peramivir is an option for these patients if there are contraindications to or concerns about reduced bioavailability of oral oseltamivir.^{18,28} Inhaled zanamivir is not recommended for patients with severe disease because it has not been well studied. It is contraindicated in patients requiring mechanical ventilation and in those with underlying lung disease because of

TABLE 4 (continued)

Treatment of Influenza

Drug/formulation	Cost*	Dosages	FDA-approved indications	Contraindications and precautions
Peramivir (Rapivab), available as solution for injection	\$1,000	Adults and children 13 years and older: single dose of 600 mg Children 2 to 12 years of age: single dose of 12 mg per kg (up to 600 mg)	Treatment of uncomplicated acute influenza A and B in patients 2 years and older who have been symptomatic for no more than 48 hours	Contraindicated in people with serious hypersensitivity or anaphylaxis to peramivir or any component of the product Potential adverse effects include diarrhea, nausea, vomiting, and neutropenia Weigh risks and benefits during pregnancy; no human data available; no known risk of embryo-fetal toxicity based on animal data at 8 times the recommended human dose; possible risk of embryo-fetal toxicity with continuous intravenous infusion based on limited animal data
Baloxavir (Xofluza), available as oral tablets	NA (\$160)	Adults and children 12 years and older: 88 to 174 lb (40 to 79 kg): single dose of 40 mg ≥ 175 lb (80 kg): single dose of 80 mg	Treatment of uncomplicated acute influenza in patients 12 years and older who have been symptomatic for no more than 48 hours	Contraindicated in people with a history of hypersensitivity to baloxavir or any component of the product Potential adverse effects include diarrhea, bronchitis, nasopharyngitis, headache, and nausea Avoid use during pregnancy; no human data available; no known risk of fetal harm based on animal data at 5 and 7 times the maximum recommended human dose

FDA = U.S. Food and Drug Administration; NA = not available.

*—Estimated retail cost for one treatment course based on information obtained at <http://www.goodrx.com> (accessed September 12, 2019). Generic price listed first; brand name in parentheses.

the risk of bronchospasm.^{18,28} Adamantanes (amantadine and rimantadine [Flumadine]) are approved for influenza treatment but are not currently recommended. These medications are not active against influenza B, and most influenza A strains have shown adamantane resistance for the past 10 years.¹⁸

There is no demonstrated benefit to treating patients with more than one antiviral agent or using higher than recommended dosages.²⁸ However, extended treatment courses may be indicated in critically ill patients.¹⁸ Supportive treatment and management of complications, including potential secondary bacterial pneumonia, are paramount. Corticosteroids are not recommended unless the patient has another approved indication for their use.^{18,28} Treatment resistance should be considered in patients who take antivirals and develop lower respiratory tract disease, although this is less likely than natural disease progression and more common in immunosuppressed patients.¹⁸

Pregnancy is an independent risk factor for complicated influenza. The risk of maternal death increases with each

trimester and continues for four weeks postpartum.²⁸ Oseltamivir has good safety data in pregnancy, and the CDC recommends it as first-line treatment for pregnant women.¹⁸ No change in dosing is necessary.

Chemoprophylaxis

Although chemoprophylaxis with NA inhibitors can prevent influenza infection, it is recommended only for specific populations¹⁸ (Table 4). Vaccination is the preferred method for prevention, and routine chemoprophylaxis within the community is not recommended.¹⁸ Clinicians can opt to closely monitor symptoms in exposed patients; early initiation of treatment is an alternative strategy.^{18,28} Indications to consider chemoprophylaxis are summarized in Table 5.^{18,28} However, most of these indications are based on poor-quality evidence and expert opinion. In a long-term care facility, an influenza outbreak is defined as two laboratory-confirmed cases within 72 hours in residents on the same unit.⁴⁰ In the setting of outbreak in a nursing care facility or hospital, chemoprophylaxis is recommended for all asymptomatic

TABLE 5

Infectious Diseases Society of America Indications to Consider Chemoprophylaxis for Influenza

Indications	Duration
Postexposure prophylaxis for people at high risk of complications of influenza should be initiated within 48 hours of initial exposure if unable to vaccinate or if vaccine effectiveness is likely to be low after close contact exposure to a person with influenza	7 days after initial exposure
Postexposure prophylaxis in conjunction with vaccination for unvaccinated people in close contact with a person at high risk of influenza complications should be initiated within 48 hours of initial exposure to a person with influenza	At least 7 days after initial exposure or until vaccine effectiveness is likely achieved
Postexposure prophylaxis in unvaccinated people at high risk of influenza complications should be initiated within 48 hours of initial exposure in conjunction with vaccination after exposure to a person with influenza	14 days or until vaccine effectiveness is likely achieved
Preexposure prophylaxis for people at high risk of developing complications of influenza if unable to vaccinate or vaccine likely to be ineffective when influenza is present (immune deficiency)	Duration of influenza activity
Preexposure prophylaxis for people at the highest risk of complications of influenza, such as hematopoietic stem cell transplant recipients within 12 months posttransplant or lung transplant recipients (people with severe immune deficiency)	Duration of influenza activity
Preexposure prophylaxis for unvaccinated people at high risk of complications of influenza in conjunction with vaccination when influenza activity is present in the community	14 days or until vaccine effectiveness is likely achieved
Preexposure prophylaxis for unvaccinated people in close contact (including health care professionals) with people at high risk of influenza complications if unable to vaccinate, high-risk contacts cannot take chemoprophylaxis, and influenza activity is present in the community	Duration of influenza activity

Note: Most of these recommendations are based on poor- to moderate-quality evidence.
